# *Trichoderma harzianum* as a biocontrol for Dollar spot disease (*Sclerotinia homoeocarpa*) on creeping bentgrass turf - 2011 trial

## K. Carey, A.J. Porter, E.M. Lyons and K.S. Jordan

Department of Plant Agriculture and the Guelph Turfgrass Institute, University of Guelph, Ontario.

The objective of this research project was to determine the efficacy of formulations of *Trichoderma harzianum* on dollar spot disease and general performance of creeping bentgrass turf maintained as a putting green.

Data collected included the disease incidence and disease severity as well as any directs effects on health of turfgrass plants

### **MATERIALS / METHODS**

The trial included five treatments (Table 1). An untreated check was included. Treatments were applied to  $1 \ge 2$  m plots of "Penn A-4" creeping bentgrass turf maintained on a USGA sand rootzone as putting green at the Guelph Turfgrass Institute (mowing at 4 mm, irrigation to prevent stress – Figure 1). Treatments were replicated four times in a randomized complete block design. All treatments were applied with a compressed air sprayer (50 ml m<sup>-2</sup> spray volume; flat fan nozzles) according to the schedule given in Table 1.

Inoculum of the disease organism (S. homoeocarpa) was prepared by growing several strains of the fungus on autoclaved Kentucky bluegrass seed. Inoculum was applied to the turfgrass at 5 g m<sup>-2</sup> July 13, 2011, when dollar spot disease was beginning to be prevalent. Relative humidity in the inoculated turf was kept high by irrigation, to stimulate disease development.

<sup>1</sup>Dollar spot inoculum added to all plots in on July 13, 2011

Figure 1. Plot area on creeping bentgrass USGA green, July 14, 2011 (6 days after first treatment application; 1 day after dollar spot inoculation).

Disease incidence and severity was assessed by visual ratings of damage, point quadrat measurement of disease area, and analysis of digital images. Response of the turf to treatments was assessed both visually and using instrumental color (canopy reflectance). Uniformity of the color response was assessed visually. Plots were rated regularly for turf quality, density and uniformity. Other stresses were measured as they occurred (disease, weed, drought). Winter survival and spring greenup will be assessed in April 2012.

All data was analysed statistically using the SAS package of statistical software.

An anecdotal photographic record was kept of the progress of the trial.

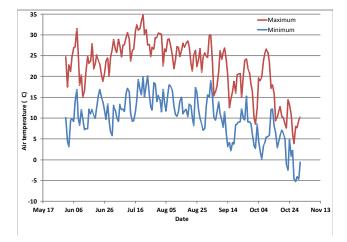

Figure 2. Daily air temperatures at GTI, summer 2011.

#### RESULTS

*Environmental data*. Daily air temperatures for June – October 2011 are presented in Figure 2.

Turf performance – canopy reflectance. The canopy reflectance measurements (Table 2) were able to detect the decline in plots with visible dollar spot infection, which became significant towards the end of August (first visible DS lesions on Aug. 3; first consistent decline in NDVI in inoculated plots on Aug. 29).

Visual ratings of dollar spot infection. The first dollar spot lesions appeared in the plots 8 days after inoculation with S. homoeocarpa spores (July 21, Table 3). Significant disease presence developed in the inoculated half of the plots by 3 weeks after inoculation (August 3). Significant patterns in the uninoculated portion of the plots were not apparent until about 6 weeks after inoculation (August 24). Until 6 weeks after inoculation, disease pressure was assessed by counting lesions in plots. At this point lesions were too numerous to count in the most heavily affected plots, so area measures were used, first point-quadrat estimates of area, and then digital image analyses of diseased area (Table 3, Figure 3).

There was a significant correlation between lesion counts and percent area affected as estimated by point-quadrat methods (Figure 4),

 $^{1}$ Normalized-difference vegetation index: mean of 4 replicates; means within columns followed by the same letter are not significantly different (Tukey's HSD test, p=0.05).

 $^{2}$ Normalized-difference vegetation index corrected against negative control mean (Control=0); means within columns followed by the same letter are not significantly different (Tukey's HSD test, p=0.05).

<sup>1</sup>Mean number of lesions per 1 m<sup>2</sup>; means within columns followed by the same letter are not significantly different (Tukey's HSD test, p=0.05). <sup>2</sup>Percent area estimated by point-quadrat; 100 points per m2. Means of 4 replicates; means within columns followed by the same letter are not significantly different (Tukey's HSD test, p=0.05).

<sup>3</sup>Percent area estimated by digital image analysis. Means of 4 replicates; means within columns followed by the same letter are not significantly different (Tukey's HSD test, p=0.05).

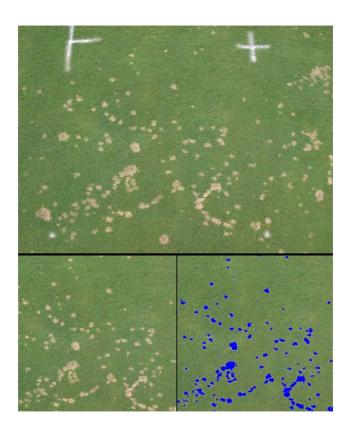

Figure 3. For digital image analyses, raw images of each 1x1 m subplot (top) were deskewed, cropped, and resized to 2000x2000 pixels in Adobe Photoshop (bottom left), and then analyzed with Sigma Scan software, which estimates dollar spot area based on color thresholds (bottom right). The actual estimate in the plot pictured was 5.8% area covered by dollar spot lesions.

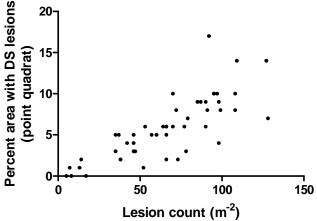

Figure 4. Association between counts of dollar spot infection centres and percent area of disease estimated by point quadrat (08/19 and 08/24). Correlation coefficient is 0.78.

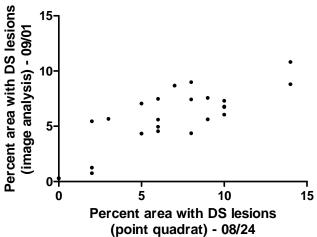

Figure 5. Association between percent area of disease estimated by point quadrat and by digital image analysis. Correlation coefficient is 0.81.

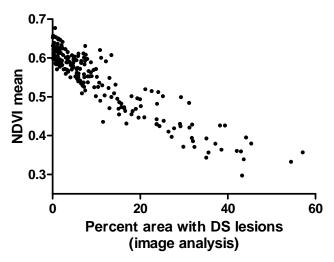

Figure 6. Association between canopy reflectance and percent area of disease estimated by digital image analysis. Correlation coefficient is -0.92.

and between point-quadrat and image analysis estimates of percent area (Figure 5). There was also a strong correlation between canopy reflectance and the area of dollar spot coverage estimated by image analysis (Figure 6).

#### DISCUSSION AND CONCLUSIONS

Based on direct estimates of dollar spot disease, whether lesion counts, point-quadrat area estimates or image analysis, the fungicide treatment was the only one to give consistent control compared to the untreated plots. The canopy reflectance data, which appeared to be detecting differences based on dollar spot disease, showed a similar pattern. Because there are other factors that affect canopy reflectance (scalping and other stresses), the NDVI values should be taken as indirect estimates of dollar spot disease.
